

Using X-rays to explore the structure of crystals

After the Laue experiment, which revealed that, because of their periodicity, crystals could cause X-rays to diffract, William Lawrence Bragg and his father, William Henry Bragg, developed the science of X-ray crystallography. This enabled them to determine the atomic structure of the crystal.

 $\lambda = 2dsin\theta$

In 1912, the Braggs analysed Laue's results in detail. At 22 years of age William Lawrence worked out an equation for calculating the position of the atoms within a crystal from the manner in which the surface planes of this crystalline structure diffract the X-rays: Bragg's Law $\lambda=2d\sin\theta$.

Delving deeper into the heart of the crystal

By as early as 1912 the Braggs had invented a new apparatus: the X-ray diffractometer (spectrometer). They took numerous measurements with their diffractometer and investigated the atomic structure of different crystals.

The Braggs received the Nobel prize for physics in 1915

The diffraction of X-rays was no longer a mere physical phenomenon; it had become a tool for exploring the arrangement of atoms within the crystals.
